

## energy storage of inductor during resonance

What is energy stored in an inductor? The energy stored in an inductor refers to the electrical energy converted into and held within the magnetic field generated by the current flowing through its coil. Unlike resistors that dissipate energy as heat or capacitors that store it in an electric field, an inductor temporarily "banks" energy in its magnetic flux. How does an inductor work? Unlike capacitors which store energy in an electric field between two conductive plates, or batteries which store energy chemically, an inductor converts electrical energy into magnetic potential energy. When current flows through its coil, it generates a magnetic field in the surrounding space and, often, within a ferromagnetic core. How do you calculate energy stored in an inductor? The instantaneous power in an inductor is  $P = V \cdot I$ , and since  $V = L \frac{dI}{dt}$ , the power is  $P = L \frac{dI}{dt} I$ . Integrating this power over time as the current increases from zero to a steady value  $I$  gives the total energy stored. Formula: The energy ( $E$ ) stored in an inductor is given by:  $E = \frac{1}{2} LI^2$  Where:  $E$  is the energy stored, measured in Joules (J). How does a Magnetic Inductor store energy? Instead, the energy is stored in the magnetic field as the rising current forces the magnetic lines of force to expand against their tendency to become as short as possible--somewhat as a rubber band stores energy when it is stretched. Figure 1 Determining the energy stored by an inductor What happens when an inductor reaches a steady-state value? When the current in a practical inductor reaches its steady-state value of  $I_m = E/R$ , the magnetic field ceases to expand. The voltage across the inductance has dropped to zero, so the power  $p = vi$  is also zero. Thus, the energy stored by the inductor increases only while the current is building up to its steady-state value. How does a solar energy storage inductor work? In this topology, the energy storage inductor is charged from two different directions which generates output AC current. This topology with two additional switching devices compared to topologies with four switching devices makes the grounding of both the grid and PV modules. Fig. 12.
