

## how to calculate the heat storage capacity of energy storage bricks

What is the heat capacity of a brick wall? Sample calculations of heat capacity for several brick walls are provided in Figure 1. Brick walls with a nominal thickness or 4 in. or greater have heat capacities greater than or equal to 6 Btu/ft<sup>2</sup>. Each energy code and standard is slightly different in scope and criteria for compliance. Can a brick wall have a heat capacity of 6 BTU/ft<sup>2</sup>? Use of the adjustment factors for mass walls in the International Residential Code and the International Energy Conservation Code is limited to walls having a heat capacity greater than or equal to 6 Btu/ft<sup>2</sup>. Sample calculations of heat capacity for several brick walls are provided in Figure 1. Does brick masonry save energy? Brick masonry, as a high mass building material, has the inherent energy saving feature of thermal storage capacity (thermal mass). This Technical Notes describes how to quantify thermal mass and calculate the heat capacity of several brick masonry walls. What is total heat capacity? Heat capacity represents the amount of thermal energy which may be stored by a material. For walls constructed of multiple materials, total heat capacity is calculated as the sum of the heat capacities of the individual components. How is the heat capacity of a wall calculated? In most energy codes and standards in the United States, heat capacity (HC) of a wall is calculated as the product of weight per unit area and specific heat ( $HC = w \times c$ ). Since the specific heats of most building materials are roughly equal, the heat capacity of a wall is directly proportional to its weight. How is energy stored as sensible heat in different types of materials? Energy stored as sensible heat in different types of materials. Thermal energy can be stored as sensible heat in a material by raising its temperature. The heat or energy storage can be calculated as Heat is stored in 2 m<sup>3</sup> granite by heating it from 20 oC to 40 oC. The density of granite is kg/m<sup>3</sup> and the specific heat of granite is 790 J/kg°C. One regular brick weights 2.3Kg, has 1000J/Kg/K specific heat capacity (0.278Wh/Kg/K) and costs \$0.50 in bulk. Heated to 1500C one brick stores  $0.278 \times 2.3 = 959$ Wh of heat.  $\$0.5/0.959 = \$0.52/\text{kWh}$  (t) storage capacity cost. Compare this to \$100/kWh (e) storage cost for batteries.
