A battery is made up of an anode, cathode, separator, electrolyte, and two current collectors (positive and negative). The anode and cathode store the lithium. The electrolyte carries positively charged lithium ions from the anode to the cathode and vice versa through the separator. The movement of Battery Energy Storage Systems (BESS) are rapidly transforming the way we produce, store, and use energy. These systems are designed to store electrical energy in batteries, which can then be deployed during peak demand times or when renewable energy sources aren't generating power, such as at night. In part because of lithium's small atomic weight and radius (third only to hydrogen and helium), Li-ion batteries are capable of having a very high voltage and charge storage per unit mass and unit volume. Li-ion batteries can use a number of different materials as electrodes. The most common type is graphite. A battery energy storage system (BESS) captures energy from renewable and non-renewable sources and stores it in rechargeable batteries (storage devices) for later use. A battery is a Direct Current (DC) device and when needed, the electrochemical energy is discharged from the battery to meet demand. Lithium-ion batteries have revolutionized the way we store and use energy. With their high energy density, long cycle life, and declining costs, these batteries have become the cornerstone of modern energy storage solutions, powering everything from smartphones to electric vehicles and large-scale storage. A battery energy storage system (BESS) stores electricity in rechargeable batteries when supply exceeds demand or during off-peak hours, and releases it when demand rises. It relies on a Battery Management System (BMS) to control charging, discharging, and safety, a Power Conversion System (PCS) to convert the stored energy into alternating current (AC).
