The Korea Institute of Machinery and Materials (KIMM), under the National Research Council of Science and Technology (NST), has successfully developed and demonstrated key technologies for a Liquid Air Energy Storage (LAES) system--recognized as a next-generation solution for large-scale energy storage. During charging, air is refrigerated to approximately $-190\text{ }^{\circ}\text{C}$ via electrically driven compression and subsequent expansion. It is then liquefied and stored at low pressure in an insulated cryogenic tank. To recover the stored energy, a highly energy-efficient pump compresses the liquid air to $-196\text{ }^{\circ}\text{C}$ and expands it back to atmospheric pressure, producing electricity. LAES systems represent a cutting-edge solution for large-scale energy storage, offering a means to stabilise electrical grids increasingly dominated by intermittent renewable generation. By utilising off-peak or surplus electricity to liquefy air at approximately $-196\text{ }^{\circ}\text{C}$, LAES systems store energy as cryogenic liquid, which can later be expanded to recover power. A mini-review on liquid air energy storage system hybridization

Liquid air energy storage (LAES) is a medium-to large-scale energy system used to store and produce energy, and recently, it could compete with other storage systems (e.g., compressed air energy storage (CAES)). It uses cryogen, or liquid air, as its energy vector. This study, for the first time, employed systematic, content, and bibliometric review approaches to provide an overview of LAES systems. In recent years, liquid air energy storage (LAES) has gained prominence as an alternative to existing large-scale electrical energy storage systems. LAES systems are becoming increasingly important in balancing and optimizing grid efficiency due to the growing penetration of renewable energy. LAES systems are thermal energy storage systems which take electrical and thermal energy as inputs, create a thermal energy reservoir, and produce electricity.
