Flywheel energy storage (FES) works by accelerating a rotor (flywheel) to a very high speed and maintaining the energy in the system as rotational energy. When energy is extracted from the system, the flywheel's rotational speed is reduced as a consequence of the principle of conservation of energy; adding energy to the system correspondingly results in an increase in the speed of the flywheel. Flywheel energy storage is a sophisticated technology harnessing kinetic energy to provide a multitude of applications, particularly in energy management systems. By employing a rotating mass, flywheel systems store energy mechanically, allowing for quick discharge and recharge cycles. By employing a rotating mass, flywheel systems store energy mechanically, allowing for quick discharge and recharge cycles. This is the fundamental principle behind an FES system is rooted in basic physics - specifically, the concept of rotational energy. Energy input: The system starts with an external power source. This can be from the grid, a renewable source, or any other form of electricity. This energy is used to set the flywheel spinning. Flywheel Energy Storage Systems (FESS) rely on a mechanical working principle: An electric motor is used to spin a rotor of high inertia up to 20,000-50,000 rpm. Electrical energy is thus converted to kinetic energy for storage. For discharging, the motor acts as a generator, braking the rotor to a stop. At its core, flywheel energy storage operates on the principle of kinetic energy. A flywheel is essentially a heavy rotating mass, usually made of high-strength materials like carbon fiber or steel. When energy is available, such as from a power grid during off-peak hours or from renewable sources, the flywheel is spun up.
